Human respiratory system - Human respiratory system - The mechanics of breathing: Air moves in and out of the lungs in response to differences in pressure. When the air pressure within the alveolar spaces falls below atmospheric pressure, air enters the lungs (inspiration), provided the larynx is open; when the air pressure within the alveoli exceeds atmospheric pressure, air is blown from the lungs (expiration).

Basic respiratory mechanics AIMS: The mechanics of breathing is best described in terms of airways resistance and lung compliance. However, these measurements are not readily available in clinical practice and instead clinicians must focus on the indirect information available from spirometry. The great advantage of

Abstract. Respiratory mechanics refers to the expression of lung function through measures of pressure and flow. From these measurements, a variety of derived indices can be determined, such as volume, compliance, resistance, and work of breathing. Plateau pressure is a measure of end-inspiratory distending pressure.

Mechanical ventilation is a life-support system used to maintain adequate lung function in patients who are critically ill or undergoing general anesthesia. The benefits and harms of mechanical ventilation depend not only on the operator's setting of the machine (input), but also on their interpretation of ventilator-derived parameters (outputs), which should guide ventilator strategies.

Volume/ ?Pressure. Compliance. • Static Compliance. -Measured during no gas flow (i.e., no ?V) -Reflects the elastic properties of the lung. • Tendency to recoil toward its original dimensions after removing distending pressure. • Dynamic Compliance. -Measured during continuous breathing -Reflects elastic as well as resistive components -Measures from end of expiration to the end of inspiration for a given volume.
